Suppression of disturbances

The weight is

$$W_S(s) = \dots$$

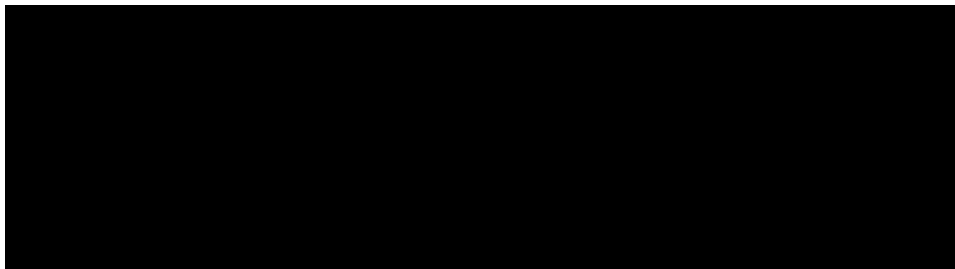

Figure 1: Simulation results with system G , using W_S .

How much is the disturbance damped on the output? What amplification is required for a P-controller to get the same performance, and what are the disadvantages of such a controller?

.....
.....

Robustness

What is the condition on T to guarantee stability according to the small gain theorem, and how can it be used to choose the weight W_T ?

.....
.....

The weights are

$$W_S(s) = \dots$$

$$W_T(s) = \dots$$

Is the small gain theorem fulfilled?

.....

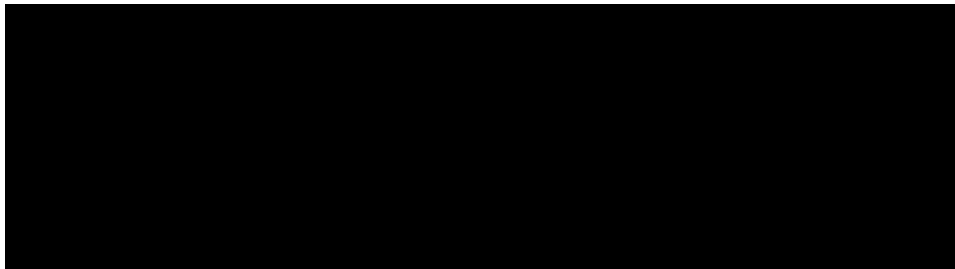

Figure 2: Bode diagram showing that the small gain theorem is satisfied.

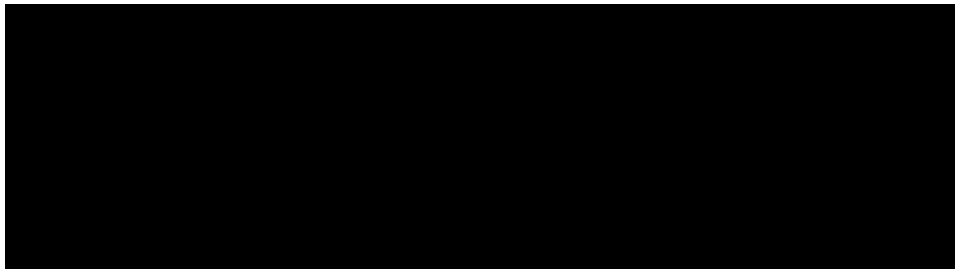

Figure 3: Simulation results with system G_0 , using W_S and W_T .

Compare the results to the previous simulation

.....

Control signal

The weights are

$$W_S(s) = \dots$$

$$W_T(s) = \dots$$

$$W_U(s) = \dots$$

Compare the results to the previous simulations

.....

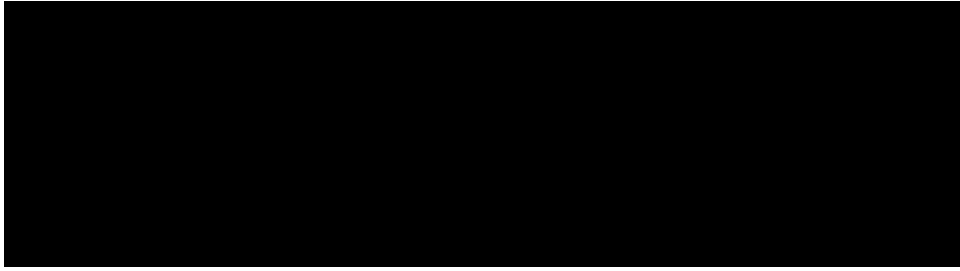

Figure 4: Simulation results with system G_0 , using W_S , W_T and W_U .
